

# Type Prediction in Source Code with Graph Neural Network Embeddings

Vitaly Romanov

# Introduction

## Source code analysis with ML

# Introduction

## Source code analysis with ML

# Introduction

## Source code analysis with ML

```
def sum(xs: List[Int]) -> Int:  
  val acc = 0  
  for x in xs:  
    acc += x  
  return acc
```

Type prediction

```
def sum(xs: List[Int]) -> ???:  
  acc = 0  
  for x in xs:  
    acc += x  
  return acc
```

Variable Name  
Prediction

```
def sum(xs):  
  ??? = 0  
  for x in xs:  
    ??? += x  
  return ???
```

Translation

```
int sum(int [] xs){  
  int acc = 0;  
  for(x:xs)  
    acc += x;  
  return acc;  
}
```

Summarization

**Summary:**  
A function to  
compute a sum of  
elements in a list

Clone detection

```
def sum(xs):  
  return sum(xs)
```

# Introduction

## Source code analysis with ML

```
from ExampleModule import ExampleClass  
instance = ExampleClass(None)  
  
def main():  
    print(instance.method1())  
  
main()
```

Majority of ML for source code is done  
using token representation of code  
(Naturalness hypotheses, Allamanis 2017)

Recent approaches explore using graph  
representation of source code

# Introduction

## Summary

- All ML tasks for source code require some level of understanding to process source code
- It would be beneficial to have a shared model
- Such models called pre-trained model
- Pre-trained models are widely adopted for images and text (BERT, ResNet)
- Existing pre-trained models for code are borrowed from NLP
- Pre-trained models specific for source code are not well studied, hard to evaluate
- Good pre-trained models will enable faster development of intelligent tools

# Introduction

## Contributions

- Trained Graph Neural Network (GNN) embeddings for source code
- Performed experiments with different pre-training objectives
- Tested pre-trained embeddings on the task of type prediction for Python variables
- Studied the impact of GNN embedding dimensionality on the type prediction quality
- Tested a technique for combining existing NLP-based approaches with GNN embeddings

# Existing Work

## Evaluation Challenges

- Pre-trained models enable faster training
- Pre-trained models allow achieve better prediction quality on various tasks
- They are not straightforward to evaluate due to disconnect between pre-training task and evaluation tasks
- Evaluation tasks for source code are not well defined

# Existing Work

## Results

| Method                            | Pre-training tasks                                                      | Evaluation Tasks                                                           |

| Classifier     |                      |      |      |       |      |       |      |   |        |        |
|                | O                    | O    | O    | U-Int | O    | U-Str | O    | O | O      | O      |

# Background

## NLP after ~2005-2008

- To prevent feature space explosion, use dimensionality reduction
- Obtain token embeddings by decomposing token collocation matrix from a large dataset (**pre-training**)

$$A = E \cdot E^T, A_{ij} = 1 \text{ if token } t_i \text{ collocates with token } t_j$$

- Rows of  $E$  are token embeddings

# Background

## NLP after ~2008-2010

$A = E \cdot E^T, A_{ij} = 1$  if token  $t_i$  collocates with token  $t_j$

- $A \in R^{|V| \times |V|}$
- $E \in R^{|V| \times d}$ , d - embedding dimensionality
- Rows of  $E$  are token embeddings
- Features are no longer explainable, need to learn black box classifier
- Context is limited, but larger than before

# Background

## NLP state-of-the-art

- Modern methods trained with Masked Language Model (MLM) objective
- Context size is large
- Pre-train entire model instead of only token embeddings

# Background

## NLP state-of-the-art

- Most of the model is reused for new task
- Classifier in the end substituted for task-specific classifier

# Background

## NLP models summary

| Classical NLP                                                          | Early applications of embeddings                                                | State-of-the-art NLP                                                          |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <b>High dimensional</b> discrete features                              | Embedding vectors as <b>low dimensional</b> features                            | Embedding vectors are <b>contextual</b> and require a pre-trained model       |
| Features are <b>hand crafted</b>                                       | <b>Embeddings</b> are trained automatically to recover <b>word collocations</b> | Embedding <b>model</b> pre-trained to recover <b>missing tokens</b>           |
| Trained for <b>specific task</b>                                       | Embeddings are pre-trained on large corpus and <b>reused</b> across tasks       | Embedding model is pre-trained on large corpus and <b>reused</b> across tasks |
| Increasing <b>context size</b> leads to <b>exploding</b> feature space | <b>Context size is small</b> due to limited computational resources             | <b>Context size is large</b> and requires a lot of computational resources    |

# Examples of Embeddings for Source Code

Example of projecting vectors for tokens in C/C++ source code to 2D space (Harer et al. 2018)

# Background

## Drawbacks of NLP models for Source Code

Problems:

- Source code is represented as a sequence of tokens
- Sequential representation does not reflect source code execution order
- Context size is limited and cannot incorporate imports and calls
- Elements of source code are processed as strings and not as aliased entities

Solution

- Use Graph Neural Networks

# Method Description

## Source Code Processing Pipeline

# Method Description

## Transform Source Code Into a Graph

- Abstract Syntax Tree (AST) was chosen as a starting point for building graph representation of source code
- Additional edges added to connect different parts of source code (inheritance, calls, imports)
- Nodes that represent the same variable in a function are connected together
- Reduce the number of parameters with subword tokenization

# Method Description

## Transform Source Code Into a Graph

# Method Description

## Transform Source Code Into a Graph

# Method Description

## Transform Source Code Into a Graph

# Transform Source Code Into a Graph

# Method Description

## Transform Source Code Into a Graph

# Method Description

## GNN

- Graph Neural Network (GNN) is a class of Neural Network that takes graph as an input
- GNNs are based on the principle of message passing
- Messages are vector representations of nodes

# Method Description

## GNN Message Passing Algorithm

---

**Algorithm 1:** Message passing algorithm for GNN

---

**Data:** Input graph

**Result:** Model that produces embeddings for nodes in the graph

initialize node embeddings randomly;

**while** *training* **do**

**for** *n message passing steps* **do**

        for each node, prepare message from it's own embedding;

        for each node, pass message to neighbours;

        for each node, aggregate messages from neighbours;

        for each node, update it's own embedding;

**end**

    for nodes in training set, compute loss function;

    to minimize loss, update embeddings and GNN parameters;

**end**

---

# Method Description

## Difference between GNN and Transformer

Both models aim at producing embeddings for source code. These models share similarity In how embeddings are computed

Transformer creates fully connected graph between each token in current context. Embeddings created for tokens.

GNN model uses only connections defined in the original graph. Embeddings created for nodes.

# Method Description

## Pre-training objectives

We experiment with several pre-training objectives

- Name prediction
- Edge prediction
- Node type prediction
- TransR objective (variant of edge prediction)

# Method Description

## Pre-training objectives

# Method Description

## Pre-training outcome

- The outcome of pre-training process is a GNN model that can be used for computing GNN embeddings
- GNN embeddings are not the same as token embeddings in NLP approaches
- GNN embeddings can be used for classifying individual nodes and for classifying subgraphs
- At the current stage, experiments completed only for classifying variables by type (node classification)

# Type prediction

## Approaches for Type Prediction

- Classify embedding for node that represents variable (Type Prediction I)
- Use hybrid model to take advantage from sequential and graph representations (Type Prediction II)

# Type prediction

## Approach for Type Prediction I

```
def sum(xs: List[Numbers]) -> int:  
    """
```

Takes a list of integers,  
returns an integer  
"""

```
    acc: int = 0  
    for x in xs:  
        acc += x.value  
    return acc
```

# Type prediction

## Approach for Type Prediction II

```
def sum(xs: List[Numbers]) -> int:
    """
    Takes a list of integers,
    returns an integer
    """
    acc: int = 0
    for x in xs:
        acc += x.value
    return acc
```

```
def sum ( xs ) : \n \t acc = 0 \n \t for x in xs: \n \t \t acc += x . value \n \t return acc
```

# Type prediction

## Approach for Type Prediction II

# Experiments

## Data Preparation

- Remove type annotations and default values from code and graph
- Pre-train GNN model
- Compute embeddings for nodes that represent variables
- Simplify type annotations (`List[Int]`  $\rightarrow$  `List`)
- Overall 2767 examples and 89 unique type labels
- Use top 20 type labels (80%) as popular types

# Experiments

Need to determine:

1. Are pre-trained graph embeddings useful for type prediction?
2. How type prediction quality is affected by embedding dimensionality?
3. Can GNN embeddings be used together with sequential embeddings?
4. Do GNN embeddings improve training speed?

# Experiment

## Are pre-trained graph embeddings useful for type prediction?

- Pre-train GNN embeddings using pre-training objective
- Pre-training objective is not related to type prediction
- Take embeddings for nodes that correspond to variables
- Classify embeddings into Python types
- Random embeddings are used as baseline

Type Prediction I

# Experiments

How type prediction quality is affected by embedding dimensionality?

- Dimensionality of GNN embeddings can be controlled
- Increasing dimensionality leads to better performance
- CodeBERT (dimensionality 768) provided for reference

# Experiments

## What are common mistakes?

- Vertical axis - correct type
- Horizontal - predicted type
- A lot of confusion with popular types (str, any)
- Confusion among ambiguous types (Union, List)

# Experiments

## Can GNN embeddings be used together with sequential embeddings?

- Need to determine
- Are pre-trained graph embeddings useful for type prediction?
- How type prediction quality is affected by embedding dimensionality?
- Can GNN embeddings be used together with sequential embeddings?
- Do GNN embeddings improve training speed?

Type Prediction II

# Experiments

## Type Prediction Examples

### Predicted

```
def _update_inplace( self FRAMEORSERIES , result STR , verify_is_copy BOOL ) :  
  
    # NOTE: This does *not* call __finalize__ and that's an explicit  
    # decision that we may revisit in the future.  
  
    self._reset_cache()  
    self._clear_item_cache()  
    self._data = getattr(result, "_data", result)  
    self._maybe_update_cacher(verify_is_copy=verify_is_copy)
```

### Ground Truth

```
def _update_inplace(self, result, verify_is_copy BOOL_T ) :  
  
    # NOTE: This does *not* call __finalize__ and that's an explicit  
    # decision that we may revisit in the future.  
  
    self._reset_cache()  
    self._clear_item_cache()  
    self._data = getattr(result, "_data", result)  
    self._maybe_update_cacher(verify_is_copy=verify_is_copy)
```

# Experiments

## Type Prediction Examples

### Predicted

```
def __init__(self, string STR ) :  
    if not isinstance(string, str):  
        raise TypeError("IsEqualIgnoringCase requires string")  
    self.original_string = string  
    self.lowered_string = string.lower()
```

### Ground Truth

```
def __init__(self, string STR ) :  
    if not isinstance(string, str):  
        raise TypeError("IsEqualIgnoringCase requires string")  
    self.original_string = string  
    self.lowered_string = string.lower()
```

# Experiments

## Type Prediction Examples

### Predicted

```
def parse_config_file( path STR , final BOOL ) :  
    return options.parse_config_file(path, final=final)
```

### Ground Truth

```
def parse_config_file( path STR , final BOOL ) :  
    return options.parse_config_file(path, final=final)
```

# Experiments

## Do GNN embeddings improve training speed?

- ML models are trained in iterations (epochs)
- Pre-trained model improves training speed for Type Prediction II
- Top prediction accuracy improved

$$\text{Improvement}_i = \text{Score\_with\_GNN}_i - \text{Score\_without\_GNN}_i$$

# Summary

- Created a GNN model for creating source code embeddings
- Designed an approach to use sequential representation of source code (NLP) together with graph representations
- Evaluated pertained embeddings on the task of type prediction for Python variables. Compared results with CodeBERT
- Using CodeBERT together with GNN embeddings allow to improve type prediction accuracy
- GNN embeddings improve training speed
- Pre-training gives best results using Name Prediction objective

# Future Work

- Better to test on larger dataset
- Current results for the prediction achieved for simplified types. Can explore approaches for predicting full type
- Need to evaluate on other tasks (variable misuse, search)

# Thank you
